Same Storm, Different Boats: Generative AI and the Age Gradient in Hiring

Magnus Lodefalk[a,b] • Lydia Löthman[a] • Michael Koch[c] • Erik Engberg[a,b]

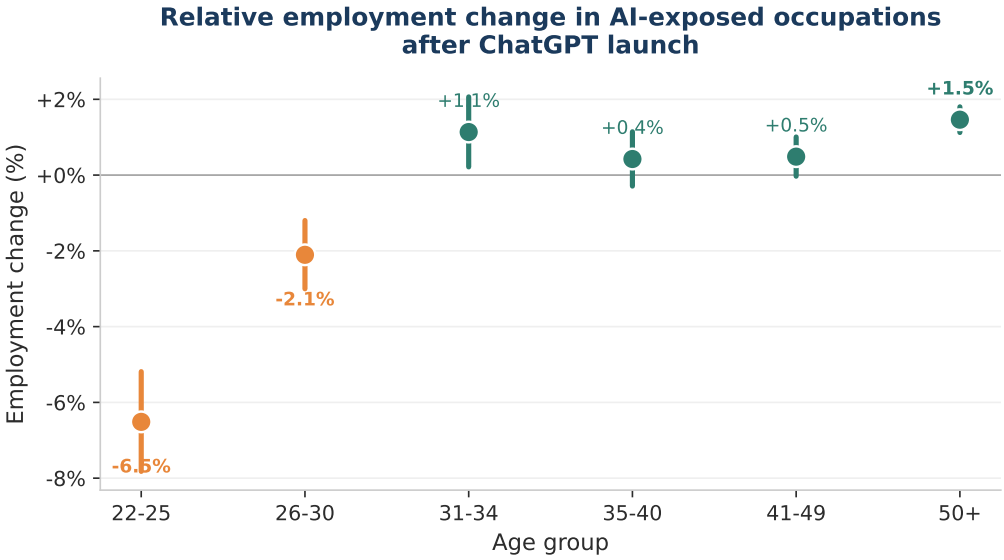
Key finding: In the two years after ChatGPT's launch, employment of **22–25 year olds** in AI-exposed occupations fell by **6.5%** relative to less exposed occupations, while employment of **workers over 50 rose by 1.5%**.



Note: Employer×quartile and employer×month fixed effects. 95% CI shown. Bold = $p < 0.01$.

What we found

- The widely noted decline in job postings is more consistent with **monetary tightening** (the 2023 Riksbank rate hike) than with AI-driven demand suppression.
- Beneath this aggregate trend, AI is reshaping **who gets hired**. Within the same firms, young workers in AI-exposed occupations are disproportionately losing employment, a shift invisible in aggregate statistics.
- The age gradient is **monotonic**: the younger the worker, the larger the negative effect. An event study with flat pre-trends shows the gap **widening through mid-2025**, though hiring has not yet been distinguished from separations. Using Swedish **full-population** register data, the result mirrors US findings (Brynjolfsson et al., 2025), complements a Danish intensive-margin null (Humlum & Vestergaard, 2024), and contrasts with a Finnish occupation-level null (Kauhanen, 2025); our within-employer design may capture composition shifts not visible at the occupation level.

Policy implications

- **AI operates on employment composition**, not only aggregate demand. Targeted interventions are needed alongside broader economic policy.
- Candidate responses include **entry-level transition pathways**: vocational education (YH) and apprenticeships integrating AI tools, though their effectiveness for this specific challenge remains to be tested.
- **The silver lining**: evidence shows young workers recover faster from displacement than older workers (Athey et al., 2024), making early intervention particularly promising.
- Monitoring the **composition** of employment, not just the volume, is essential for timely policy response.

Data & method: Swedish administrative register data (AGI) covering the full working-age population, monthly, 2019–June 2025. Outcome: employment positions by age group and occupation. AI exposure measured using the DAIOE index (Engberg et al., 2024). Difference-in-differences with employer×quartile and employer×month fixed effects, following Brynjolfsson et al. (2025). SEs clustered by employer. DAIOE is constructed from pre-2022 work content, fixed across the sample period. No correlation between occupational interest-rate sensitivity and AI exposure ($r \approx 0$). **7 March 2026**

Preliminary results. Working paper forthcoming 13 March 2026. Part of AISCAF (WASP-HS) and the AI-Econ Lab at Örebro University and Ratio.
